VERIFICATION PHASE

VERIFICATION

Execute Query

`execute_query(query)`

Executes a SPARQL query against the Knowledge Graph and returns the results.

Purpose: Serves a dual role: running the final query to obtain the answer, and providing iterative feedback throughout reasoning. Use it to test intermediate query drafts and diagnose errors in partial queries.
Use LIMIT to prevent fetching too much data for verification queries. After verification, the final query you return should be consistent with the question on whether LIMIT is needed.

Output Format: Table with the query result columns, or an error message if the query fails.

INPUT SCHEMA

query string REQ

The valid SPARQL query string to execute.

OUTPUT FORMAT

Table with the query result columns, or an error message if the query fails.

FINISH

Answer Question

`answer(kg, sparql, answer)`

Provide your final SPARQL query and answer to the user question based on the query results. This function will stop the generation process.

INPUT SCHEMA

kg string REQ

The knowledge graph on which the final SPARQL query needs to be executed

sparql string REQ

The final SPARQL query

answer string REQ

The answer to the question based on the SPARQL query results

OUTPUT FORMAT

Stops the generation process and returns the final answer.
